

Studies of **wildlife habitat relationships** are complicated by the spatial and temporal complexity of habitat use. Radio-tracking data collected over a certain time period is often matched with uni-temporal definitions of land cover units or other environmental parameters. In this study we aimed at determining how is our understanding of habitat use by two badger species affected by using environmental data collected at three temporal resolutions:

- (i) uni-temporal data collected in the summer,
- (ii) seasonal data collected once per season,
- (iii) multi-temporal data collected each month.

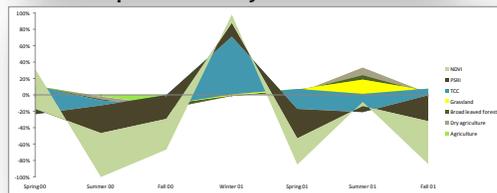

Goal: Use multi-temporal imagery to detect commonalities of badger habitat use in two Mediterranean oak woodlands.

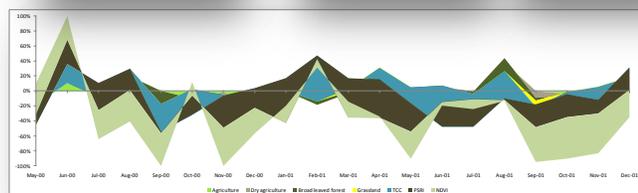

Eurasian badger (*Meles meles*)
